(Received 8 May 2017, revised 30 May, accepted 1 June 2018)

Abstract: Pressure, density and temperature (p , ρ , T) data and apparent molar volumes, V_ϕ° , of aqueous calcium acetate solutions $\text{Ca}(\text{CH}_3\text{COO})_2(\text{aq})$ over a wide range of temperatures from 273.15 to 353.15 K, pressures up to $p = 100$ MPa and molalities m , of 0.04918, 0.09367, 0.23797, 0.36365, 0.85923, 1.06930, 1.35223 and 1.81668 mol·kg⁻¹ of $\text{Ca}(\text{CH}_3\text{COO})_2$ are reported. The combined expanded uncertainty of the density (ρ) measurements at the 95 % confidence level with a coverage factor of $k = 2$ was estimated to be $U_c(\rho) = \pm 0.3$ kg·m⁻³. The measurements were realized with an Anton Paar DMA HPM vibration tube density meter. The system was calibrated using double-distilled water, aqueous NaCl solutions, methanol, toluene and acetone. An equation of state for fitting of the (p , ρ , T) data of aqueous calcium acetate was developed as a function of pressure, temperature and molality. After a thorough analysis of literature values and validity of the constructed equation of state, various thermophysical properties, such as isothermal compressibility, isobaric thermal expansibility, differences in isobaric and isochoric heat capacities, thermal pressure coefficient and internal pressure at the investigated state parameter intervals were calculated.

Keywords: density; aqueous calcium acetate solution; apparent molar volume; isothermal compressibility; isobaric thermal expansibility.

INTRODUCTION

It is accepted that the main reason of global warming is the increment of the concentration of greenhouse gases, especially CO₂. The most effective way to combat and prevent the increasing concentration of CO₂ in the atmosphere is to

*Corresponding author. E-mail: javid.safarov@uni-rostock.de
<https://doi.org/10.2298/JSC080517049U>

capture and store it, or preferably utilize it. Many technologies have been developed to capture CO₂, such as, absorption, adsorption, cryogenic separation, membrane separation or microbial/algal systems. Amongst these systems, the mostly used one in post-combustion systems is absorption of CO₂ with appropriate solutions.¹ In conventional systems for the capture of CO₂ mostly acyclic primary amine, acyclic secondary or tertiary amine solutions or cyclic amine-based solutions (piperazine, morpholine, *etc.*) or their mixtures are used.² In post-combustion carbon dioxide absorption systems, cooled flue gas is first sent to the absorber in which the carbon dioxide in the flue gas is contacted with an amine solution. Here, the absorber is typically operated at 40–60 °C to ensure high affinity for CO₂ absorption.³ After the flue gas is water-washed to balance water in the system and to remove any solvent droplets or solvent vapor, it can be emitted to the atmosphere. The rich solvent (CO₂ containing solvent) stream leaves the absorber and is sent to the regeneration unit. The stripper here is operated at high temperature (100–140 °C) and pressure (1.5–2 atm) to ensure lower affinity for CO₂ absorption.^{3,4} In the stripper, the desorption process is endothermic, heat must be applied to the absorbent to maintain its temperature. However, the operation of such systems is very energy consuming due to the high pressure and temperature values in the absorption and desorption units, thus decreasing the overall power plant efficiency. Moreover, systems with amine solutions have some more drawbacks, such as low loading capacity (kg CO₂ per kg of solvent), high degradation of solvents with SO₂ and O₂ that may be present in flue gas, high equipment corrosion rate, high degradation of solvents at high temperatures and high volatility.^{1,5,6} Thus, alternative solutions are being investigated. Due to its alkaline nature and the ability to react with CO₂ at ambient temperatures, calcium acetate Ca(CH₃COO)₂ could be a better alternative. The overall reaction between CO₂ and Ca(CH₃COO)₂ is:⁷

In order to investigate the reaction kinetics and mass transfer effects in this reaction, first it is important to obtain the values of thermophysical parameters: pressure, density and temperature (*p*, *ρ*, *T*) of aqueous Ca(CH₃COO)₂ solutions.

Analysis of the literature density results^{8,9} at high pressures and over a temperature range of 283.15–308.15 K (Table I) showed the necessity of careful experimental (*p*, *ρ*, *T*) measurements of Ca(CH₃COO)₂(aq) over a wide range of temperatures and pressures. Saury *et al.*⁸ in 1993 investigated the solubility of Ca(CH₃COO)₂ in the temperature range 273.15–373.15 K, at ambient pressure and molar concentrations from 0.35 to 1.77 mol·L⁻¹. The authors demonstrated that the solubilities of calcium acetate monohydrate and hemihydrate in aqueous solution decrease with increasing temperature, the former and later phases being stable below and above *T* = 331.15 K, respectively. They also analyzed the density of Ca(CH₃COO)₂ concentrations at *T* of 283.15–318.15 K.

TABLE I. A literature revision of experimental works dedicated to the thermodynamic properties of $\text{Ca}(\text{CH}_3\text{COO})_2(\text{aq})$, $p = 0.101 \text{ MPa}$

Ref.	Year	Properties	T / K	$c / \text{mol} \cdot \text{L}^{-1}$
8	1993	Density	283.15–308.15	0.35 to 1.77
9	1964	Density	298.15	0.06 to 1.57

Some density points are given in the chemistry handbook edited by Nikolskiy⁹ in 1965. These values were determined at $T = 298.15 \text{ K}$, at ambient pressure and in the 0.06–1.57 mol L⁻¹ molar concentration range of $\text{Ca}(\text{CH}_3\text{COO})_2$.

Since, There are no high-pressure values of the thermophysical properties of $\text{Ca}(\text{CH}_3\text{COO})_2(\text{aq})$ in the literature and only two works with ambient pressure values of density over a small range of temperatures were found.

This paper is a continuation of previous publications on the thermophysical properties of aqueous electrolyte solutions.^{10–14} In the present paper, the (p, ρ, T) properties, and apparent molar volumes, V_ϕ , of $\text{Ca}(\text{CH}_3\text{COO})_2(\text{aq})$ over a wide range of temperatures from 273.15 to 353.15 K, pressures up to $p = 100 \text{ MPa}$ and molalities of 0.04918, 0.09367, 0.23797, 0.36365, 0.85923, 1.06930, 1.35223 and 1.81668 mol·kg⁻¹ of calcium acetate are reported for the first time, and the apparent molar volumes at infinite dilution, V_ϕ^0 , have been evaluated. An empirical correlation for apparent molar volumes of $\text{Ca}(\text{CH}_3\text{COO})_2$ (aq) with pressure, temperature and molality has been derived.

EXPERIMENTAL

Calcium acetate (product No.: C1000; CAS No.: 62-54-4, molecular weight: 0.1581672 kg·mol⁻¹, chemical formula: $\text{Ca}(\text{CH}_3\text{COO})_2$) was purchased from Sigma–Aldrich (BASF, quality, $\geq 99 \%$). In order to remove all volatile impurities, the sample was dried under vacuum for 48 h at a temperature of 423.15 K. The mass fraction of water determined after drying by means of a Karl–Fisher titration was $w = 10^{-4}$ mass fraction. Double distilled water was used for the preparation of the solutions.

The (p, ρ, T) measurements were performed using a modernized high pressure – high temperature Anton-Paar DMA HPM vibration tube densimeter, which is based on the dependence of the period of oscillation of a unilaterally fixed U-tube (Hastelloy C-276) on its mass. The sample in the oscillating tube is part of a complex system. Inertia shear forces occur on the wall, influencing the resonant frequency of the oscillator. The mPDS2000V3 control unit measures the vibration period with an accuracy of $\Delta\tau = \pm 0.001 \mu\text{s}$. The temperature in the measurement cell, where the U-tube is located, is controlled using a thermostat (F32-ME Julabo, Germany) with a $\Delta T = \pm 10 \text{ mK}$ uncertainty of the measurement and is measured using the (ITS-90) Pt100 thermometer (type 2141) with a $\Delta T = \pm 15 \text{ mK}$ experimental uncertainty of the measurement. The pressure was measured using different pressure transmitters for precision measurements (WIKA Alexander Wiegand GmbH & Co., Germany) with a $\pm 0.1 \%$ standard uncertainty of the measured maximum value: for pressure $0.101 < p < 0.25 \text{ MPa}$ and for pressure $0.25 < p < 2.5 \text{ MPa}$ two different model of pressure transmitter P-30 and for pressure $2.5 < p < 100 \text{ MPa}$ pressure transmitter P-10.

The (p, ρ, T) properties over a wide range of temperatures from 273.15 to 353.15 K and pressures up to $p = 100 \text{ MPa}$ were measured up to maximum solubility of the salt in water

($m = 1.81668 \text{ mol}\cdot\text{kg}^{-1}$). This method gives the viscosity effect of vibration tubes. However, the viscosity of the prepared samples was not high enough for this effect to require attention. The system was calibrated using double-distilled water, aqueous NaCl solutions, *etc.* As NaCl(aq) up to maximum molality (also electrolyte water solution) was used during the calibration, in this case, the viscosity influence was considered during the calibration procedures. The deviation between the corrected viscosity and non-corrected viscosity values of Ca(CH₃COO)₂(aq) was smaller than the combined expanded uncertainty of the density ρ measurements. According to the specifications of Anton Paar and the calibration procedures, the observed repeatability of the density measurements in this work at temperatures from 273.15 to 353.15 K and pressures up to $p = 100 \text{ MPa}$ was within $\Delta\rho = \pm 0.3 \text{ kg}\cdot\text{m}^{-3}$ or 0.01 to 0.03 % percent deviation (at the 95 % confidence level with a coverage factor of $k = 2$).^{15,16}

The density of Ca(CH₃COO)₂(aq) at ambient pressure and at temperatures from 273.15 to 353.15 K was measured using the Anton Paar DSA 5000M and DMA HPM vibration tube densimeters with an uncertainty of $\pm 5 \times 10^{-3}$ and $\pm 0.3 \text{ kg}\cdot\text{m}^{-3}$, respectively. These values are necessary to check the accuracy of ambient pressure density measurements using the high pressure – high temperature DMA HPM vibration tube densimeter. The standard deviation between ambient pressure density measured using the Anton Paar DSA 5000M and DMA HPM vibration tube densimeters were smaller than $\Delta\rho = \pm 0.35 \text{ kg}\cdot\text{m}^{-3}$.

Specific quantities of calcium acetate and water were evacuated, degassed in two separate flasks and connected using an adapter.¹⁷ Water flowed into another flask and the concentration of the solution was defined using the weight of the flask with the solution on an electronic scale (Sartorius ED224S, Germany) with reproducibility of $\pm 0.0001 \text{ g}$.

RESULTS AND DISCUSSION

In the present paper, the (p, ρ, T) properties, and apparent molar volumes V_ϕ of Ca(CH₃COO)₂(aq) over a wide range of temperatures from 273.15 to 353.15 K, pressures up to $p = 100 \text{ MPa}$ and molalities of 0.04918, 0.09367, 0.23797, 0.36365, 0.85923, 1.06930, 1.35223 and 1.81668 mol·kg⁻¹ of Ca(CH₃COO)₂ are reported for the first time. The experimental values of density, ρ , isothermal compressibility, κ_T , isobaric thermal expansibility, α_p , difference in isobaric and isochoric heat capacities, $c_p - c_v$, thermal pressure coefficient, γ , internal pressure, p_{int} , of Ca(CH₃COO)₂(aq) are listed in Table S-I of the Supplementary material to this paper.

Using a program for standard thermodynamic analysis to describe the (p, ρ, T) properties of Ca(CH₃COO)₂(aq), the equation of state (1) from the literature¹⁸ was used:

$$p(\rho, T) / \text{MPa} = A(T)(\rho / \text{g cm}^{-3})^2 + B(T)(\rho / \text{g cm}^{-3})^8 + C(T)(\rho / \text{g cm}^{-3})^{12} \quad (1)$$

where A , B and C are the coefficients and all are functions of temperature and molality in the following form:

$$A = \sum_{i=1}^4 T^i \sum_{j=0}^3 a_{ij} m^j, \quad B = \sum_{i=0}^3 T^i \sum_{j=0}^3 b_{ij} m^j, \quad C = \sum_{i=0}^3 T^i \sum_{j=0}^3 c_{ij} m^j \quad (2)$$

The a_{ij} , b_{ij} and c_{ij} are the coefficients of the polynomials and are tabulated in Table II. The Eqs. (1) and (2) reproduce the experimental values with $\Delta\rho/\rho = \pm 0.014\%$ average deviation. Figs. 1–3 show the plot of pressure p of $\text{Ca}(\text{CH}_3\text{COO})_2\text{(aq)}$ against density ρ at $m = 1.35223 \text{ mol}\cdot\text{kg}^{-1}$, plot of density ρ of $\text{Ca}(\text{CH}_3\text{COO})_2\text{(aq)}$ against pressure p at $T = 298.15 \text{ K}$ and of the deviations of the experimental density ($\rho_{\text{exp.}}$) of the investigated samples from the calculated density ($\rho_{\text{cal.}}$) obtained from Eqs. (1) and (2) vs. pressure p at T from 273.15 to 353.15 K, respectively. Fig. 4 show the plot of deviations of ambient pressure density measured using DSA 5000M densimeter ρ_{DSA5000M} from the measured using DMA HPM densimeter $\rho_{\text{DMA HPM}}$ of the investigated samples against temperature T / K at various molalities of CaAc.

The apparent molar volumes V_ϕ of the $\text{Ca}(\text{CH}_3\text{COO})_2$ in water are defined by Eq. (3) and are listed in Table S-II of the Supplementary material:

$$V_\phi = 1000(\rho_w - \rho_s)/(m\rho_s\rho_w) + M/\rho_s, \quad (3)$$

where ρ_w and ρ_s are densities of the water and solution, g/cm^3 , and m is the molality of solution, mol kg^{-1} , and M is the molar mass of the dissolved $\text{Ca}(\text{CH}_3\text{COO})_2$, g mol^{-1} .

The uncertainty in derived values of V_ϕ depends strongly on m , ρ_w and ρ_s . The maximum relative uncertainty, ΔV_ϕ , in the apparent molar volume V_ϕ can be estimated using the following equation:

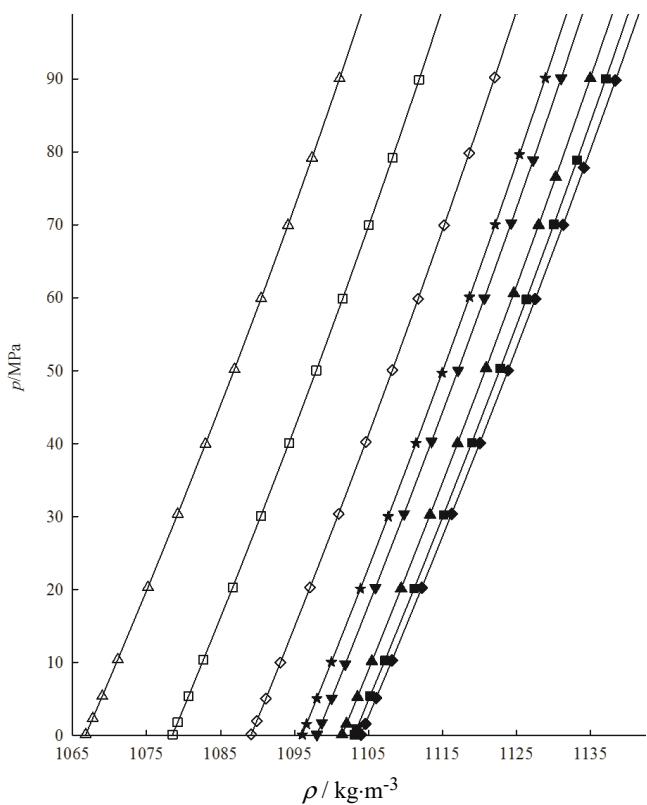

Fig. 1. Plot of pressure of $\text{Ca}(\text{CH}_3\text{COO})_2\text{(aq)}$ against density at $m = 1.35223 \text{ mol}\cdot\text{kg}^{-1}$ at the temperature of: \blacklozenge , 273.16; \blacksquare , 277.15; \blacktriangle , 283.15; \blacktriangledown , 293.15; \star , 298.15; \lozenge , 313.15; \square , 333.15; \triangle , 353.15 K; —, fitted to Eqs. (1) and (2).

$$\delta V_\phi = \left(1 - \frac{Mm}{1000}\right) \left(\frac{\rho_w}{\rho_w - \rho_s} \right) \delta \rho_s + \left(\frac{\rho_s}{\rho_w - \rho_s} \right) \delta \rho_w + \delta m, \quad (4)$$

where δV_ϕ is the uncertainties in the apparent molar volumes, $\delta \rho_w = \pm 0.001\%$ is the uncertainty in the IAPWS pure water, $\delta \rho_s = \pm 0.03\%$ is the uncertainty in the solution density, and $\delta m = \pm 0.75\%$ (at low concentrations) and $\pm 0.06\%$ (at high concentrations) are the uncertainty in the concentration, respectively. The average uncertainties of δV_ϕ at the investigated concentrations are $\delta V_\phi = 6.67, 3.59, 1.41, 0.91, 0.34, 0.27, 0.19, 0.12\%$, respectively.

The plots of apparent molar volumes, $V_\phi / \text{cm}^3\cdot\text{mol}^{-1}$, of $\text{Ca}(\text{CH}_3\text{COO})_2$ in water *versus* molality, $m / \text{mol}\cdot\text{kg}^{-1}$, at $T = 283.15 \text{ K}$ are shown in Fig. 5. The plots of apparent molar volumes of $\text{Ca}(\text{CH}_3\text{COO})_2$ in water against pressure at $m = 1.81668 \text{ mol}\cdot\text{kg}^{-1}$ are shown in Fig. 6.

Plots of apparent molar volumes of $\text{Ca}(\text{CH}_3\text{COO})_2$ in water against pressure at $m = 1.81668 \text{ mol}\cdot\text{kg}^{-1}$ the temperature of: \blacklozenge , 273.16; \blacksquare , 277.15; \blacktriangle , 283.15; \blacktriangledown , 293.15; \star , 298.15; \lozenge , 313.15; \square , 333.15; \triangle , 353.15 K; —, fitting lines.

The apparent molar volume of $\text{Ca}(\text{CH}_3\text{COO})_2$ at infinite dilution, V_ϕ° , at constant temperature and pressure can be evaluated from the following equation:

$$V_\phi = V_\phi^\circ + A_v m^{0.5} + B_v m \quad (5)$$

where A_v is the Debye–Hückel limiting slope, m is the molality and B_v is an adjustable parameter. Redlich *et al.*^{19,20} attempted to prove the Masson hypothesis for deriving A_v by using the Debye–Hückel theory:²¹

$$A_v = kw^{3/2} \quad (6)$$

where: k and w were expressed as:

$$k = N_A^2 e^3 \left(\frac{8\pi}{1000 D^3 R T} \right)^{0.5} \frac{\partial \ln D}{\partial p} - \frac{\beta}{3} \quad (7)$$

and

$$w = 0.5 \sum_i v_i z_i^2 \quad (8)$$

where N_A is Avogadro's number, e is the electric charge, D is the dielectric constant of the solvent, R is the gas constant, T is the absolute temperature, β is

the compressibility of the solvent, v_i is the number of ions of species i and valency z_i formed by one molecule of electrolyte. According to Eq. (8) for an electrolyte of a fixed valence type, w is constant and the limiting slope A_v depends only on the temperature and the physical properties of the solvent D , $\partial \ln D / \partial p$ and β . As a rule, this relationship is applied at fixed pressure p and temperature T . The infinite-dilution values V_ϕ^0 of the apparent molar volumes V_ϕ are obtained by polynomial extrapolation of Eq. (5) to zero molality of the solution ($m = 0$). Archer and Wang²² calculated the values of A_v for 1:1 electrolytes ($w = 1$). The value $w = 3$ was used for $\text{Ca}(\text{CH}_3\text{COO})_2$ during the calculations. The apparent molar volumes of calcium acetate at infinite dilution V_ϕ^0 are listed in Table III and the adjustable parameter B_v in Table IV.

CONCLUSIONS

The thermophysical properties (p, ρ, T) of aqueous $\text{Ca}(\text{CH}_3\text{COO})_2$ solutions of eight different concentrations, at temperatures of 273.15 to 353.15 K and pressures up to 100 MPa were experimentally investigated. The measurements were performed at molalities of 0.04918, 0.09367, 0.23797, 0.36365, 0.85923, 1.06930, 1.35223 and 1.81668 $\text{mol}\cdot\text{kg}^{-1}$ of calcium acetate. A thermodynamic equation of state (1) over a well specified range of state parameters was constructed, which was applied for the calculation of the apparent molar volumes, V_ϕ , $\text{cm}^3\cdot\text{mol}^{-1}$, of $\text{Ca}(\text{CH}_3\text{COO})_2$ in water. The Debye–Hückel theory for the investigated solutions was examined. These investigations were examined for the first time and the data gathered here could contribute greatly to further work in this field.

The apparent molar volumes of $\text{Ca}(\text{CH}_3\text{COO})_2\text{(aq)}$ at 273.15 to 353.15 K and pressures up to 100 MPa are reported, and the apparent molar volumes of $\text{Ca}(\text{CH}_3\text{COO})_2$ at infinite dilution V_ϕ° were evaluated.

SUPPLEMENTARY MATERIAL

The experimental values of density, ρ , isothermal compressibility, κ_T , isobaric thermal expansibility, α_p , difference in isobaric and isochoric heat capacities, $c_p - c_v$, thermal pressure coefficient, γ , internal pressure, p_{int} , and the apparent molar volumes, V_ϕ , of the $\text{Ca}(\text{CH}_3\text{COO})_2$ in the water are available electronically at the pages of journal website: <http://www.shd.org.rs/JSCS/>, or from the corresponding author on request.

Представљени су (p, ρ, T) подаци и првидне моларне запремине, V_ϕ , водених раствора калцијум-ацетата, $\text{Ca}(\text{CH}_3\text{COO})_2\text{(aq)}$, у широком опсегу температура, од 273,15 до 353,15 K, притисцима до $p = 100$ MPa и молалитетима од 0,04918; 0,09367; 0,23797; 0,36365; 0,85923; 1,06930; 1,35223 и 1,81668 $\text{mol}\cdot\text{kg}^{-1}$. Проширења комбинована несигурност мерења густине, нивоа поузданости од 95 % и фактора покривености $k = 2$, је процењена на $U_c(\rho) = 0,3 \text{ kg}\cdot\text{m}^{-3}$. Мерења су извршена коришћењем Anton Paar DMA НРМ густиномера са вибрирајућом цеви. Систем за мерење је калибрисан применом двоструко дестиловане воде, водених раствора NaCl, метанола, толуена и ацетона. Развијена је једначина стања за корелисање (p, ρ, T) података водених раствора калцијум-ацетата као функција притиска, температуре и молалитета. Након детаљне анализе литературих вредности и валидности изведене једначине стања, прорачуната су разна термо-

динамичка својства као што су изотермска компресибилност, изобарска топлотна експанзивност, разлике изобарског и изохорског топлотног капацитета, топлотни коефицијент притиска и унутрашњи притисак на испитиваним опсезима параметара стања.
